SiPMs in Direct ToF Ranging Applications

March 2016

This white paper is intended to assist in the development of SiPM (Silicon Photomultiplier) based LiDAR (Light Detection and Ranging) systems. The following sections contain information on the design and implementation of a direct ToF (Time-of-Flight) rangefinder, in terms of the laser, timing and optical parameters and detailed analysis of key aspects that must be considered when integrating SiPMs in such systems.

1. INTRODUCTION

LiDAR is a ranging technique that is increasingly being employed in applications such as mobile range finding, automotive ADAS (Advanced Driver Assistance Systems), gesture recognition and 3D mapping. Employing an SiPM as the photosensor has a number of advantages over alternative sensor technologies such as APD, PIN diode and PMT particularly for mobile and high volume products. SensL SiPMs can offer:

- Single Photon detection from 250nm to 1100nm
- Low voltage – easy to implement system requirements
- Low power – lower operating voltages and simple readout electronics allow a low power design
- High bandwidth and fast response time – minimize range measurement time
- Ability to take advantage of low laser power direct ToF ranging techniques
- Low noise and high gain – good signal to noise ratio (SNR) is achievable
- Standard CMOS fabrication process – low cost, highly uniform and scalable production
- Small size SMT packaging – 1mm sensors available

Transitioning to SiPM sensor technology presents a different set of constraints when compared to other sensors. This white paper is intended to help the user maximise the benefits of the technology and achieve a working set-up with SiPM sensors as quickly as possible. To this end, SensL has created three tools to aid the user; a MATLAB ranging model for simulation purposes, a Ranging Demonstrator hardware set-up and this document.

- A detailed MATLAB model of a direct ToF system has been created to facilitate the simulation of an SiPM-based ranging application. The model can be used to support ranging system design and may be modified to simulate a wide variety of applications and implementations.
- A Ranging Demonstrator evaluation system has been built and is used to introduce direct ToF with SiPM sensors. In addition the results of measurements using the Ranging Demonstrator are used to validate simulation results from the MATLAB model.
- This document is intended to assist the new user in the development of SiPM-based, direct ToF ranging systems. It addresses the impact of the various system and environmental factors on the resulting signal to noise ratio.
2. Design of a Direct ToF Ranging System

The basic components required for a direct ToF ranging system, as illustrated in Figure 1, are:

1. A pulsed laser with collimation optics
2. A sensor with detection optics
3. Timing and data processing electronics

This document focuses on system design of the laser, sensor, readout and application environment. The single-point, direct ToF baseline work performed in this white paper may be extended to more complex scanning and imaging systems.

In the direct ToF technique, a periodic laser pulse is directed at the target, typically with eye-safe power and wavelength in the infrared region. The target diffuses and reflects the laser photons and some of the photons are reflected back towards the sensor. The sensor converts the detected laser photons (and some detected photons due to noise) to electrical signals that are then timestamped by the timing electronics. This time of flight, $t$, can be used to calculate the distance, $D$, to the target from the equation $D = \frac{c \Delta t}{2}$, where $c =$ speed of light and $\Delta t =$ time of flight. The sensor must discriminate returned laser photons from the noise (ambient light). At least one timestamp is captured per laser pulse. This is known as a single-shot measurement. The signal to noise ratio can be dramatically improved when the data from many single-shot measurements are combined to produce a ranging measurement from which the timing of the detected laser pulses can be extracted with high precision and accuracy.

Several different readout techniques exist to capture the timing information from the detected laser photon pulse, as summarized below.

### Readout Techniques for Ranging

- **LED (leading edge discrimination)** - Involves the detection of the rising edge of a multi-photon signal. Timing accuracy is determined by the ability to discriminate the rising edge of the returned optical signal. This technique is not affected by laser pulse width.

- **Full waveform digitization** - The full waveform is digitized and can be over-sampled to improve accuracy. Can be difficult to implement with short laser pulses or high repetition rate sources.

- **TCSPC (time correlated single photon counting)** - Provides the highest accuracy and greatest ambient light rejection. This technique requires that less than one signal photon is detected per laser pulse. This technique can be immune to ambient light but a short pulse duration, high repetition rate and fast timing electronics are required to achieve fast and accurate measurements.

- **SPSD (single photon synchronous detection)** - A form of TCSPC which provides high ambient light rejection. Electronics must be designed to deal with range ambiguity.
3. **Modelling a Direct ToF Ranging System**

A MATLAB model of a direct ToF system has been created. A block diagram of the model is shown in Figure 2. The purpose of the model is to predict the overall performance of a system given a set of system parameters similar to those shown in Table 1.

The first step consists of analytically calculating the light levels at the sensor (both ambient and laser light) given a chosen optical scenario which can be varied by changing the corresponding system parameters. By comparing the calculated light levels to the saturation limit of the sensor, the chosen setup can be validated as suitable for ranging. In the event that the particular setup is not suitable for ranging, improvements on the setup itself can be evaluated by varying the system parameters.

The second part of the model consists of a Monte Carlo simulator where the stochastic properties of the sensor, mainly the photon detection efficiency (PDE) and the timing jitter, are reproduced. This step allows a realistic output of the sensor to be obtained by simulation. In contrast to the analytic part, this step takes into account timing information such as the acquisition time, the repetition rate of the laser and the laser pulse width. The outcome of the Monte Carlo simulation is passed to a read out model, typically a discriminator followed by a TDC (Time to Digital Converter), which produces a histogram of timestamps from which a range measurement can be extracted.

**Figure 2.** Calculations of light levels are paired with a Monte Carlo simulator so that a full system output can be reproduced.
Symbol | System Parameter | Definition
--- | --- | ---
| | Acquisition method | This could be leading edge detection (LED) or time correlated single photon counting (TCSPC). |
\( f \) | Laser repetition rate | Clock rate of the laser. This is the same as the detector single-shot rate. |
\( W_{laser} \) | Laser pulse width | |
\( \lambda_{laser} \) | Laser wavelength | Wavelength of the laser beam. |
\( FWHM_{laser} \) | Laser FWHM | Spectral FWHM of the laser beam. |
\( P_{laser} \) | Laser peak power | Peak power of each laser pulse. |
\( \theta_{laser} \) | Laser beam divergence | The angle at which the laser beam diverges from a point source. |
\( d \) | Laser-sensor distance | The perpendicular distance between the laser diode and the sensor limits the minimum range. Ideally this should be 0. |
\( \phi \) | Collection lens aperture | A plano convex lens is placed directly in front of the sensor. Effective aperture after mounting of the lens. |
\( F_{lens} \) | Collection lens focal length | |
\( BP \) | Optical filter bandpass wavelength | Filter placed between sensor and collection lens. |
\( FWHM_{BP} \) | Optical filter FWHM | |
\( \theta_{det} \) | Sensor angle of view | The angle at which the field of view of the sensor diverges from a point source. |
\( SiPM \) | SiPM | SiPM sensor. |
\( A \) | Amplifier gain | SiPM signal amplifier. |
\( V_{th} \) | Threshold voltage | Comparator threshold. Dictates minimum light level required to be considered an event. |
\( t_{seq} \) | Acquisition time | The total time during which samples are recorded by the sensor for inclusion in the data. = 1/frame rate. |
\( LSB_{TDC} \) | TDC resolution | TDC bin size limits the single-shot resolution. The use of multiple single-shot measurements can yield resolution significantly better than the TDC bin size. |
\( R \) | Target reflectivity | |
\( D \) | Distance to target | Distance between the ranging module and the target. |
\( E_{a} \) | Ambient illuminance | The maximum illuminance on the sensor due to ambient light. |

Table 1, Variables in an SiPM direct ToF ranging system.
4. **The Ranging Histogram**

Each time the laser is pulsed the acquisition system performs a single-shot measurement. Depending on many factors including the laser power and distance to the target, the number of detected laser photons per pulse may be low. Ideally, each detected photon would be timestamped. However, number of timestamps per single-shot measurement may be limited by the dead time of the TDC. Usually, many single-shot timing measurements, each containing one or more timestamps, are combined to produce a frame. The complete timing data obtained over the course of a single frame may be plotted in the form of a histogram as shown in Figure 3. The system ranging performance is limited by the quality of the histogram data, which in turn is affected by the system parameters. There are some limiting factors and some trade-offs that can be made, as can be seen from the analysis of system parameters detailed in Section 5. The ranging histogram used below also provides a visual representation which is useful in describing the effects of various parameters on the data obtained. The basic histogram signal and timing parameters are explained below.

The histogram signal to noise ratio, $SNR_H$, is the ratio of the signal peak to the maximum noise peak:

$$SNR_H = \frac{\text{Signal peak value}}{\text{Noise peak value}}$$

In the model the following terms apply to the measurement time:

$$f = \text{laser frequency}$$

The laser repetition rate limits the maximum ToF that can be measured without ambiguity and this defines the time per single-shot measurement:

$$Single \text{ shot Measurement time, } t_{ss} = \frac{1}{f}$$

The frame size is the number of single-shot measurements per histogram. A larger frame size can improve $SNR_H$ and produce a better quality histogram. The ranging speed is defined by the frame rate:

$$frame \text{ rate} = \text{number of range measurements per second} = \frac{1}{t_{acc}}$$

**Figure 3,** Histogram example from simulation showing signal, noise and time of flight.
5. The Effect of Changing System Variables

System design parameters will vary based on the requirements of a specific application. The purpose of this section is to demonstrate, using the model of a direct ToF ranging system, how the acquired data is affected by each of seven key parameters. The effect of distance to target and ambient light level are also shown. The key points are summarized in Table 2.

The histograms shown in the following sections are obtained through simulation and each histogram can be assumed to include the entire dataset obtained in a single frame. For computational speed, the histograms shown correspond to a short acquisition time.

5.1 Reference Histogram

Figure 4 shows the reference histogram obtained by simulation under the conditions listed in the blue call-out box on the right. This configuration is used as a reference point to show the effects of alternative system parameter values.

The system parameters used in the following analysis were chosen to provide a reference point of a typical 5m ranging application. Some of the parameters were chosen for ease of simulation and illustrative purposes rather than to reflect an optimized setup.

Table 2, Summary of effects of key parameters

In each of the following sections one parameter only is modified and the simulation re-run to illustrate the effect that parameter has on the system in terms of collected data.
5.2 Laser Pulse Repetition Rate

A higher laser pulse repetition rate improves the quality of the histogram by increasing the number of single-shot measurements allowing more returned laser photons to be detected for a given acquisition time. The maximum noise peak also increases as more noise counts are acquired. But, because the noise is not correlated, overall SNR$_{H}$ increases, as shown in Figure 5.

There is an upper limit on the maximum laser repetition rate that may be chosen because the rate limits the distance to target that may be ranged without ambiguity. For example, if 300m is the maximum ranging target distance then a maximum repetition rate of 1MHz can be used. If 100m is the maximum target distance then 3MHz may be used.

![Figure 5, Effect of laser repetition rate](image)

5.3 Laser Pulse Width

A wider laser pulse width leads to a wider signal peak in the histogram, as shown in Figure 6. With a square pulse it is necessary to discriminate the leading edge of the pulse to locate only the time of flight of the first photons detected. Subsequent photons do not carry useful ToF information. For this reason shorter laser pulses are optimal. However the availability of suitable lasers may be the deciding factor in a practical setup.

5.4 Laser Wavelength

Selection of the laser wavelength is influenced by a number of factors including eye safety and availability of low cost lasers at particular wavelengths. Laser wavelength selection also influences ranging performance due to solar irradiance and sensor detection efficiency at different wavelengths.

For a system subject to solar noise, a longer wavelength may be chosen to exploit the corresponding reduction in solar irradiance at the longer wavelength. The effect can be seen from the model of solar irradiance in Figure 7.

With a laser wavelength of 940nm, the PDE of the modelled SiPM is reduced from ~1% to ~0.3%. Keeping all other parameters constant, the detection efficiency of both the laser photons and ambient light photons is reduced. For this particular setup the net effect is a reduction in \( SNR_H \) due to lower total counts, as shown in Figure 8. Of course, if another SiPM were chosen that has improved PDE at the wavelength of interest, the resulting histogram signal count would be higher and \( SNR_H \) would be improved. Similarly, other parameters may be modified to compensate for the reduced PDE.

Figure 7, Solar irradiance model

Figure 8, Effect of increased wavelength on histogram

- \( t_{acq} = 1 \text{ms} \)
- \( f = 150 \text{kHz} \)
- \( P_{\text{laser}} = 1 \text{W} \)
- \( E_v = 10 \text{klux} \)
- \( D = 10 \text{m} \)
- \( \lambda_{\text{laser}} = 940 \text{nm} \)
- \( \omega_{\text{laser}} = 250 \text{ps} \)
- \( \phi = 12 \text{mm} \)
- \( R = 92\% \)
- \( \theta_{\text{det}} = 1.4^\circ \)
- \( \text{FWHM}_{\text{BP}} = \pm 2 \text{nm} \)

\[ SNR_H = 2.7 \]
5.5 **Collection Lens Aperture**

When the lens aperture is widened, more ambient photons are detected while the number of returned laser photons remains constant.

The SiPM is now prone to saturation as is evident from the large overshoot at the start of the histogram window in Figure 9. When the sensor is saturated the laser photons can no longer be detected by the SiPM, leading to a lower signal detection rate and lower overall SNR_H.

![Figure 9, Effect of increased collection lens aperture](image)

### Parameters
- \( t_{\text{acq}} = 1\text{ms} \)
- \( f = 150\text{kHz} \)
- \( P_{\text{laser}} = 1\text{W} \)
- \( E_v = 10\text{klux} \)
- \( \lambda_{\text{laser}} = 905\text{nm} \)
- \( w_{\text{laser}} = 250\text{ps} \)
- \( \Theta = 20\text{cm} \)
- \( R = 92\% \)
- \( \theta_{\text{det}} = 1.4^\circ \)

\[ \text{SNR}_H = 0.2 \]

---

5.6 **Sensor Angle of View**

The sensor angle of view is determined by the sensor size and the focal length of the collection lens. When the sensor angle of view is increased to 20°, significantly more ambient light is incident on the SiPM. It then becomes saturated to the point that no laser pulses can be discerned by the system, as is the case in Figure 10.

It is crucial to limit the sensor angle of view to cover the field of the laser only and avoid this situation.

![Figure 10, Effect of increased sensor angle of view](image)

### Parameters
- \( t_{\text{acq}} = 1\text{ms} \)
- \( f = 150\text{kHz} \)
- \( P_{\text{laser}} = 1\text{W} \)
- \( E_v = 10\text{klux} \)
- \( \lambda_{\text{laser}} = 905\text{nm} \)
- \( w_{\text{laser}} = 250\text{ps} \)
- \( \Theta = 12\text{mm} \)
- \( R = 92\% \)
- \( \theta_{\text{det}} = 20^\circ \)

\[ \text{SNR}_H = \text{(no signal)} \]

---

**ToF Histogram**

**Time stamp (s)**

**Counts (#)**

\[ t_{\text{acq}} = 1\text{ms} \quad \text{MicroFC-10020} \]
\[ f = 150\text{kHz} \quad P_{\text{laser}} = 1\text{W} \]
\[ E_v = 10\text{klux} \quad D = 10\text{m} \]
\[ \lambda_{\text{laser}} = 905\text{nm} \quad w_{\text{laser}} = 250\text{ps} \]
\[ \Theta = 12\text{mm} \quad R = 92\% \]
\[ \theta_{\text{det}} = 20^\circ \quad \text{FWHM}_{\text{BP}} = \pm 2\text{nm} \]

**SNR_H = (no signal)**
5.7 Optical Filter Bandpass

An optical bandpass filter is used to limit the ambient noise arising from light at wavelengths other than the laser wavelength range.

In this case the optical filter bandpass range is 50nm FWHM (Full Width Half Maximum). This allows a wider range of wavelengths of ambient light through to the SiPM, increasing the measured background noise and worsening SNR_H as shown in Figure 11. In the model, the laser wavelength is exactly 905nm only and the acquired laser signal is not affected by the bandpass FWHM. In real systems, the laser center wavelength may have a relatively wide variation and this may have a bearing on the choice of bandpass filter.

![Figure 11, Effect of wider sensor optical bandpass](image)

5.8 SiPM Microcell Size

The histogram in Figure 12 shows the simulated performance of a MicroFC-10035 SiPM rather than the MicroFC-10020. The main effect is the slightly increased PDE at the wavelength of interest, leading to a marginally higher signal with a smaller corresponding increase in noise. At this ranging distance and under this configuration this change of SiPM does not have a significant effect on the simulated histogram.

![Figure 12, Effect of changing SiPM microcell size](image)

</tbody>
</table>

\[ SNR_{H} = 5.2 \]
5.9 Distance to Target

The plot in Figure 13 superimposes histograms ranging at 10m, 15m, 20m and 25m from the target. The spacing of the signal peaks on the x-axis corresponds to ToF = 2*distance/c. As the distance increases the number of acquired counts from the laser is reduced because the density of laser photons at the sensor decreases with 1/d² (where d is the sensor-target distance) but the ambient noise remains constant because the number of ambient photons diffused back from the target does not change with distance. At 30m, ranging is no longer possible using this configuration. The configuration may of course be optimized to perform ranging at this distance (refer to Section 6.3 for a setup that models ranging at long distance).

5.10 Ambient Light

Here the ambient light is increased 10 times to 100klux. With an increased number of ambient photons hitting the sensor and all other conditions remaining constant, more ambient photons are acquired for every single-shot measurement. The noise counts per bin over the entire frame increases accordingly and SNR_H is negatively affected. Figure 14 shows that the peak at 10m is still discernible and therefore ranging is still possible with this configuration at this light level, but the range capability will now be reduced.

Conversely, at low ambient light SNR_H would be improved due to lower noise counts.
6. RANGING DEMONSTRATOR DESCRIPTION

The Ranging Demonstrator is an evaluation system designed to provide an introduction to direct ToF ranging using SiPM sensors. The demonstrator features:

- Optical Interface including laser collimation lens, sensor collection lens and bandpass filter
- Laser diode and driver circuit
- SiPM sensor and discriminator circuit
- FPGA-based Time-to-Digital Converter (TDC), readout and communications interface
- PC based software.

Figure 15 shows the system block diagram.

The demonstrator uses a 905nm laser diode with a pulse width of 150ps and a peak laser power of up to 2W. The laser pulse repetition rate is 150KHz. The laser output signal is collimated by a lens with a divergence of 0.06°.

At the receiver the reflected signal is focused on the sensor using a 40mm focal length collection lens with an aperture of 11.4mm diameter. The sensor angle of view is 1.4°. The signal is also filtered by an optical bandpass filter with a FWHM of 10nm.

The detection signal chain consists of a SensL MicroFC-10020-SMT SiPM, a gain stage and a high-speed comparator, which performs leading edge discrimination, and pulse generator circuit. The resulting pulses are timestamped using either a standalone TDC or an FPGA-based TDC and data acquisition system. The acquired data is transferred to PC software via a high speed USB link.

The system software builds the histogram from the acquired data, which is plotted for analysis. A curve fitting algorithm extracts the ToF, as described in Section 4.

Software adjustable settings allow a range of configurations to be selected in order to optimize the system for a variety of applications.

The demo is portable and is powered by a 6V source.

A full list of the Ranging Demonstrator parameters is given in Table 3.
6.1 Performance of the Ranging Demonstrator

The performance of the Ranging Demonstrator has been measured in a number of use cases with varying distance to target and ambient light conditions.

A summary of the actual measured ranging data from 0m to 5m is shown in Figure 16 in the form of a ranging data histogram, the resulting measured range vs actual range characteristic and associated range error.

Table 4 summarizes the performance of the Ranging Demonstrator up to 5m, under lab conditions of 250lux ambient light.

Table 3, Ranging Demonstrator parameters for sensor-target distances up to 5m.

6.2 Validation of the Model using the Ranging Demonstrator

The model was configured with the system parameters of the demonstrator and simulated with the same distance to target and ambient light conditions. The simulated results were then compared to the measured results from the Ranging Demonstrator with good correlation as shown in Figure 17 and Figure 18. This validates the model and provides a means to design a system for different use cases.

6.3 Ranging Demonstrator Modelled to 100m

The model was then used to develop a set of system parameters that would enable the Ranging Demonstrator to perform at target distances of up to 100m. These parameter changes are shown in Table 5. Figure 19 shows the simulated histogram, Figure 20 shows the simulated range resolution at 100m, and Figure 21 the ranging over the full 10m - 100m range showing good linearity. The resulting system performance is summarized in Table 6.

7. **Further Help**

**Ranging Demonstrator Description** - This document describes the specification and operation of the Ranging Demonstrator. This demonstrator is an engineering prototype. Its purpose is to demonstrate SiPM technology in ranging applications and to provide feedback for modelling of future designs.

**Introduction to SiPM** - This document introduces the basic concepts of the Silicon Photomultiplier for those who are new to this type of sensor.

**How to Evaluate and Compare SiPM Sensors** - This document discusses some of the primary factors to be considered in the selection of the optimum SiPM.

**C-Series Datasheet** - The datasheet for the sensors used in this document.

**C-Series User Manual** - The user manual for the sensors used in this document.
